DETDESC:

LETD(21)

FIG. 1(A) on the other hand, illustrates how the same data as represented in FIG. 7 is recorded by writes equalization on the magnetic tape 24 of the second tape cassette 22. FIG. 6(B) shows the corresponding data signal produced by the read assembly 32 on retrains the writes equalized

and of FIG. 6(a) and (b) will be noted in FIG. 6(a) that each binary zero bit out of the ~~NRZI~~ equalized data contains both high and low states. However, since binary ones are recorded the same way as with NRZI, ~~NRZI~~ equalization may be considered a modification of NRZI. The corresponding ~~NRZI~~ output signal of FIG. 6(b) is essentially equivalent to the

US PAT NO: 4,942,465 [IMAGE AVAILABLE]

L2: 1 of 8

DETD(16)

differentiation of the ~~NRZI~~ output signal of FIG. 7(b), for, in FIG. 6(b), the zero crossing points of the waveform correspond to binary ones. This ~~NRZI~~ output signal needs no differentiation. Therefore, as will be understood by referring back to FIG. 4, the data signal representative of the recovered ~~NRZI~~ equalized data is directed to the flat amplifier circuit 74 and, after an ~~INVERTER~~, the differentiating amplifier circuit 92, to the shaping circuit 110. In this shaping circuit 110 the input signal representative of the ~~NRZI~~ equalized data is processed as above described with reference to FIGS. 5 and 6 to provide the same rectangular pulse.

DETD(7)

DETD(50)

The presence of the shields 9 also greatly reduces the fringing gradient effects from the twin-track ~~READ~~ during writing which may cause interference in adjacent tracks or portions of the medium. The primary reason is that the main field generated by the twin-track ~~READ/WRITE~~ ~~HEAD~~ passes through the medium rather than ~~bypasses~~ the medium as in

US PAT NO:

4,576,711

L2: 3 of 8

DETD(25)

the case for ordinary longitudinal or lateral gap ~~READ~~ recording systems. It is the fringe fields in longitudinal recording that ordinarily perform the writing function by design and these. . . have a relatively poor spatial gradient. In contrast, vertical twin track recording systems couple most of the flux from the ~~READ~~ or writing ~~READ~~ pole tips directly into the medium. There is some shielding effect nevertheless and this can be reduced to levels well. . .

BSUM(7)

A second problem that is encountered with ~~READ/WRITE HEAD~~ assemblies of this type involves the shorting of the two conductors that contact the F1 layer. During fabrication of the. . . sensor and conductors, a shorting condition occurs between the F1 layer and these conductors. Consequently, the MR sensor is electrically ~~bypassed~~ by the F1 layer at an overlapping area, so that the device is not operable.

DETD(7)

FIG. 5, 12, they introduce a generalized defect in the thin magnetic film and illustrate the method by which this defect is bypassed in the operation of the memory. The reference characters in FIGS. 5-11 which refer to the same components remain the. . . generator 65 generates magnetic bubbles and supplies them to a transfer block 71 which is under the control

US PAT NO: 3,792,450

L2: 6 of 8

DETD(7)
of a WRITE control circuit or terminal 67. Those bubbles generated by the generator 65 which are not transferred to the transfer loop. . . block 71 are destroyed in an annihilator 66 to which the generator 65 is connected by a magnetic channel. A WRITE control circuit 67 is connected to the transfer block 71 causing the transfer of bubbles from the generator 65 to the transfer loop 61. The information contained in the transfer loop 61 can be READ out by means of a READ HEAD 74. Although not shown in FIG. 6, the READ HEAD 74 is connected to an output or utilization circuit through a terminal 209. An erase control circuit READ or terminal 65 controls the transfer of bubbles from the transfer loop 61 across a transfer block 67 to an. . . a black, or filled-in, circle 82 is shown, it indicates that a bubble is present at that position. A row READ HEAD 39 is adjacent a row marker loop 78 and is controlled by a pulse coupled to an input terminal 85. Likewise, a column READ HEAD 63 is adjacent a

US PAT NO: 3,792,450

L2: 6 of 8

DETD(7)
column loop 79 and is connected to an input terminal 86. The control loop 76 has a control READ HEAD 75 and a control WRITE HEAD 77 adjacent it. Having described the basic organization of the sample memory chip 31, the method and apparatus for detecting. . .

ABSTRACT:

In . . . to store information in the form of magnetic bits on two sides. Faulty areas are located on the discs and bypassed by switching to another disc on a sector basis to ensure computer reliability. The disc memory elements receive information from a plurality of READ-WRITE HEADS which during normal operation are in flying association with the discs. For each memory disc there is a yoke assembly which includes a
